Lecture 12: Computational Graph Backpropagation

Last time...

Multilayer Perceptron

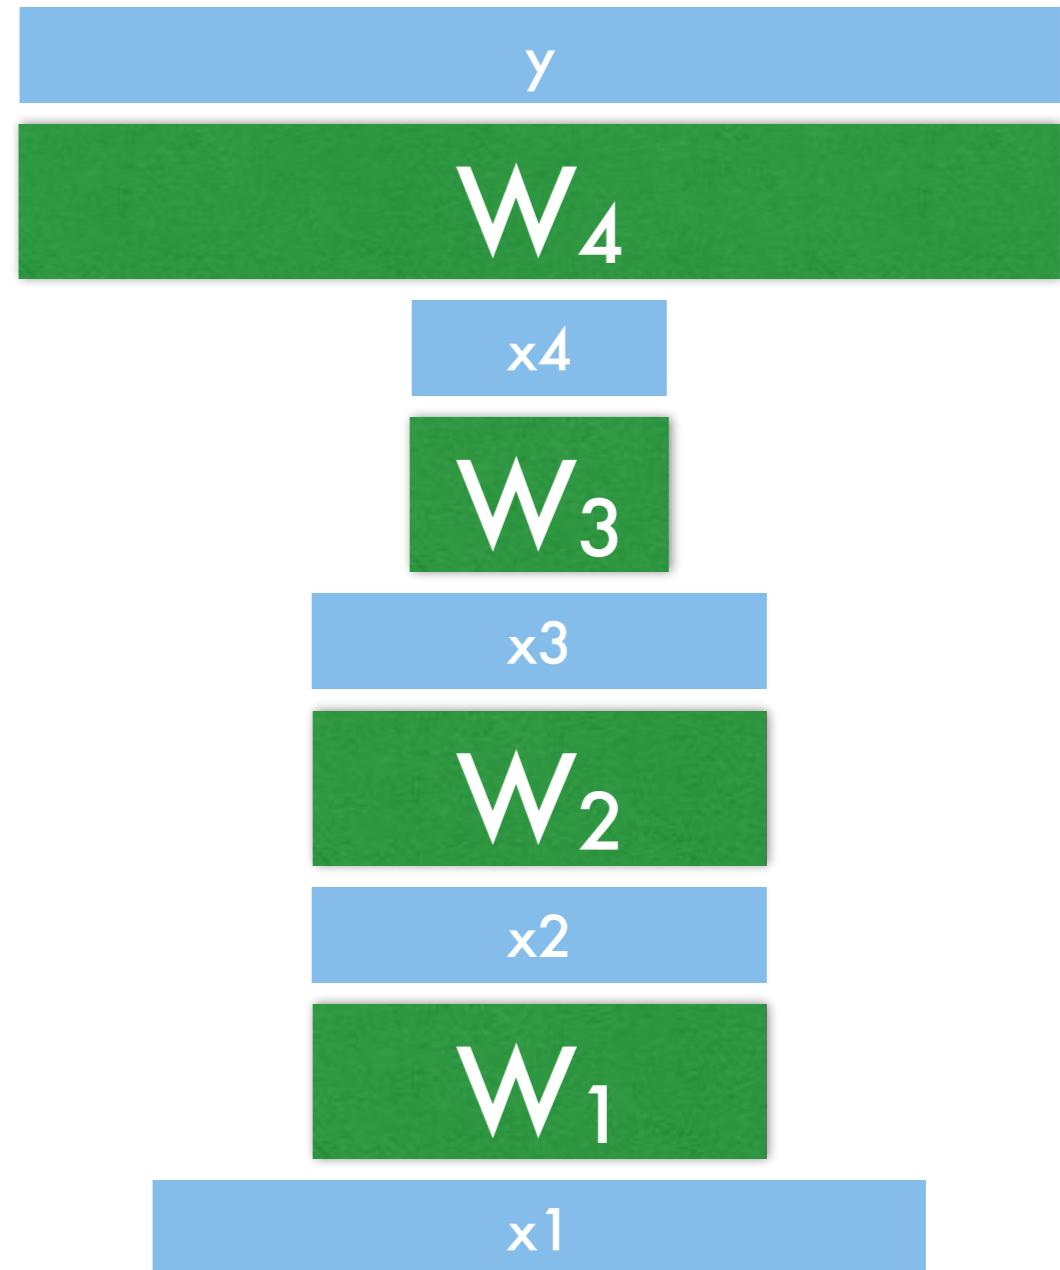

- Layer Representation

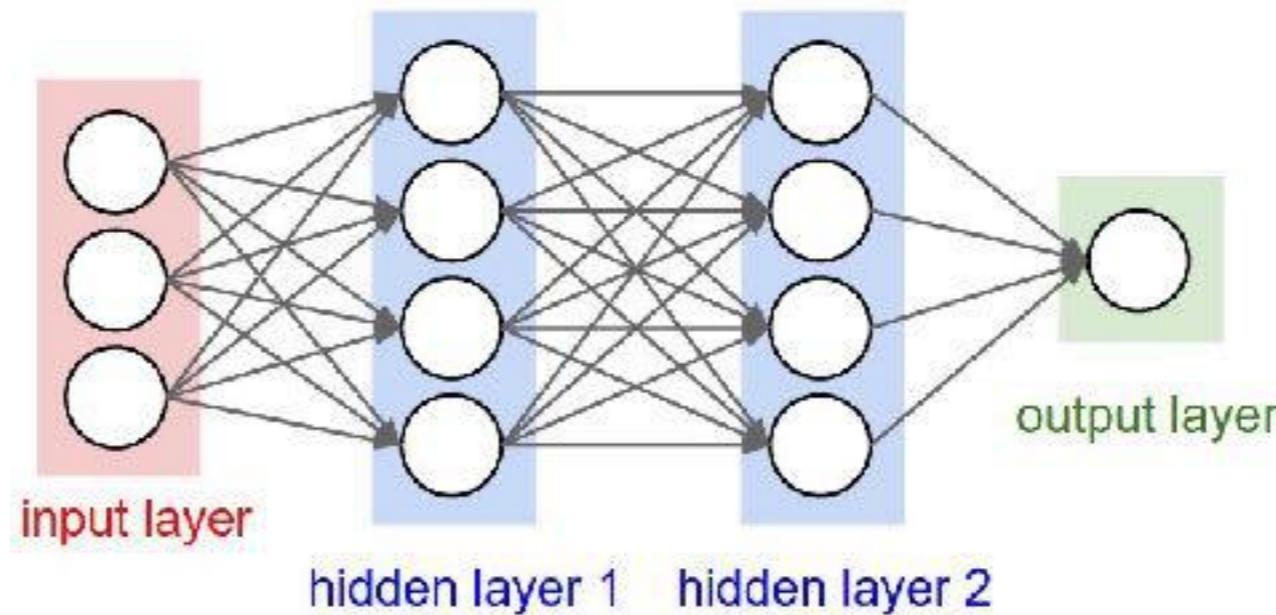

$$y_i = W_i x_i$$

$$x_{i+1} = \sigma(y_i)$$

- (typically) iterate between linear mapping Wx and nonlinear function
- Loss function $l(y, y_i)$ to measure quality of estimate so far

Last time... Forward Pass

- Output of the network can be written as:

$$h_j(\mathbf{x}) = f(v_{j0} + \sum_{i=1}^D x_i v_{ji})$$
$$o_k(\mathbf{x}) = g(w_{k0} + \sum_{j=1}^J h_j(\mathbf{x}) w_{kj})$$

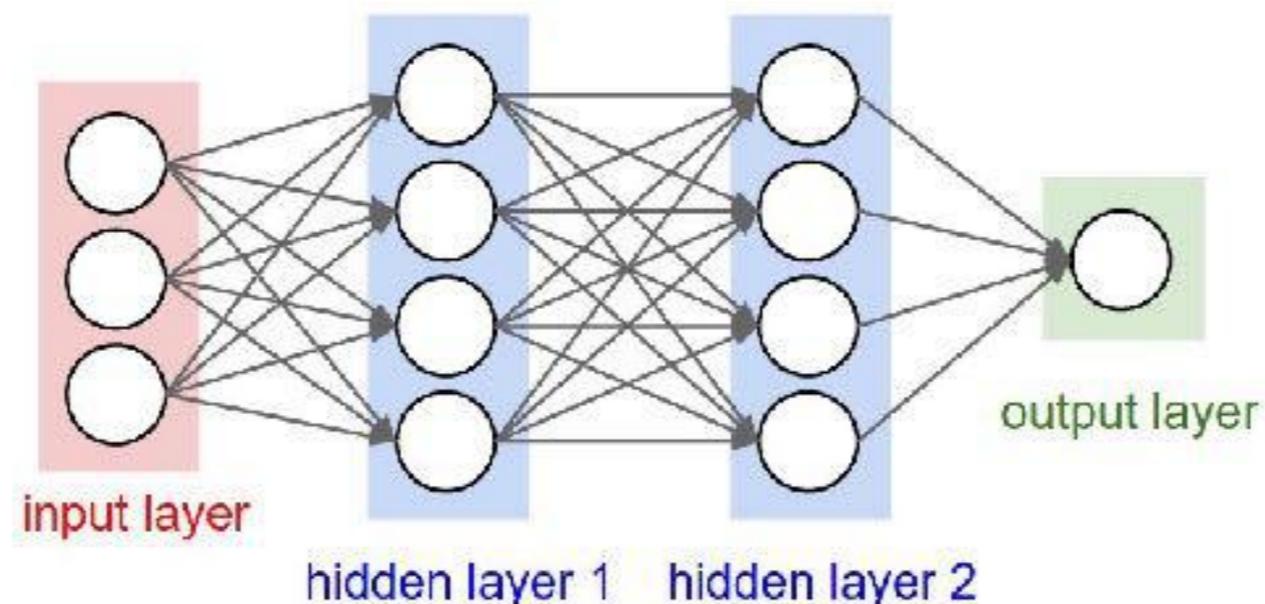

(j indexing hidden units, k indexing the output units, D number of inputs)

- Activation functions f , g : sigmoid/logistic, tanh, or rectified linear (ReLU)

$$\sigma(z) = \frac{1}{1 + \exp(-z)}, \quad \tanh(z) = \frac{\exp(z) - \exp(-z)}{\exp(z) + \exp(-z)}, \quad \text{ReLU}(z) = \max(0, z)$$

Last time... Forward Pass in Python

- Example code for a forward pass for a 3-layer network in Python:

```
# forward-pass of a 3-layer neural network:  
f = lambda x: 1.0/(1.0 + np.exp(-x)) # activation function (use sigmoid)  
x = np.random.randn(3, 1) # random input vector of three numbers (3x1)  
h1 = f(np.dot(W1, x) + b1) # calculate first hidden layer activations (4x1)  
h2 = f(np.dot(W2, h1) + b2) # calculate second hidden layer activations (4x1)  
out = np.dot(W3, h2) + b3 # output neuron (1x1)
```

- Can be implemented efficiently using matrix operations
- Example above: W_1 is matrix of size 4×3 , W_2 is 4×4 . What about biases and W_3 ?

TODO:

1. Define a **loss function** that quantifies our unhappiness with the scores across the training data.
2. Come up with a way of efficiently finding the parameters that minimize the loss function. (**optimization**)

We defined a (linear) score function:

$$f(x_i, W, b) = Wx_i + b$$

Gradient Descent

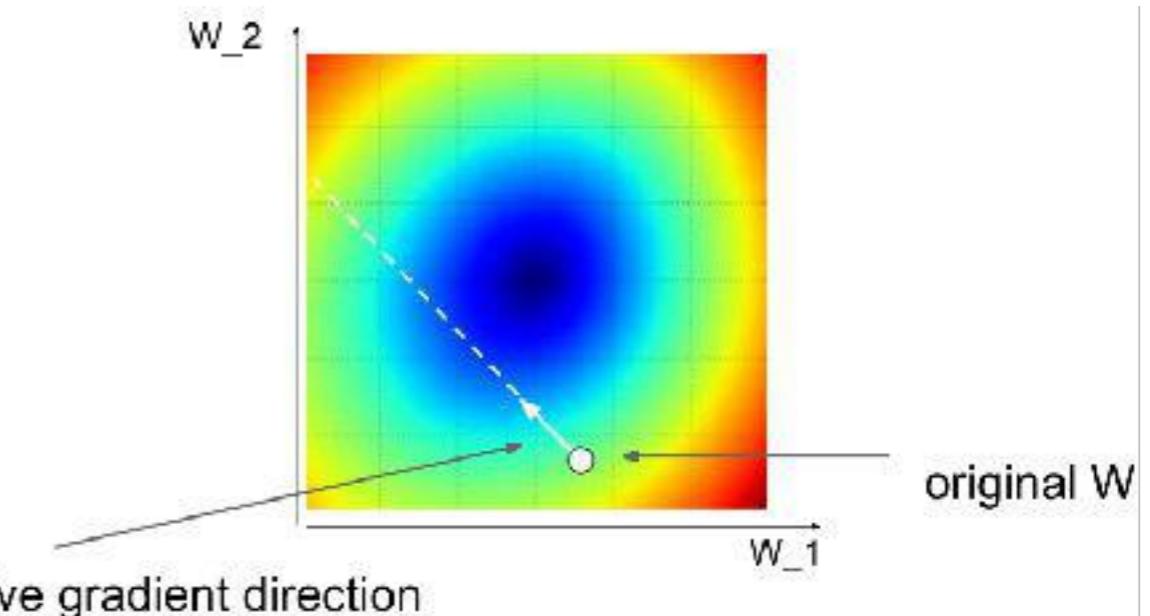

```
# Vanilla Gradient Descent  
  
while True:  
    weights_grad = evaluate_gradient(loss_fun, data, weights)  
    weights += - step_size * weights_grad # perform parameter update
```

In 1-dimension, the derivative of a function:

$$\frac{df(x)}{dx} = \lim_{h \rightarrow 0} \frac{f(x + h) - f(x)}{h}$$

In multiple dimensions, the **gradient** is the vector of (partial derivatives).

Mini-batch Gradient Descent

- only use a small portion of the training set to compute the gradient

```
# Vanilla Minibatch Gradient Descent

while True:
    data_batch = sample_training_data(data, 256) # sample 256 examples
    weights_grad = evaluate_gradient(loss_fun, data_batch, weights)
    weights += - step_size * weights_grad # perform parameter update

Summary

- neural nets will be very large: no hope of writing down gradient formula by hand for all parameters
- **backpropagation** = recursive application of the chain rule along a computational graph to compute the gradients of all inputs/parameters/intermediates
- implementations maintain a graph structure, where the nodes implement the **forward()** / **backward()** API.
- **forward**: compute result of an operation and save any intermediates needed for gradient computation in memory
- **backward**: apply the chain rule to compute the gradient of the loss function with respect to the inputs.

Where are we now...

Mini-batch SGD

Loop:

- 1. Sample** a batch of data
- 2. Forward** prop it through the graph, get loss
- 3. Backprop** to calculate the gradients
- 4. Update** the parameters using the gradient
